

Immune Plus found only in Endovac Vaccines

Immune Plus raises the overall response in the immune system of the animal. This is important both for response to vaccination as well as overall health at critical times. As the graphs below demonstrate, two key components of the immune system, lymphocytes and antibodies are both significantly increased with Immune Plus. Elevating the animal's own immune response to ward off harmful pathogens, as well as enhancing the response to all administered vaccinations, are key roles of Immune Plus.

ENDO-VAC-Dairy's Broad Spectrum of Protection

The way most vaccines are built, multiple antigens have to be added to the vaccine to get protection from multiple diseases. This cocktail method means that the animal has to respond to numerous antigens individually. The ENDO-VAC-Dairy vaccine is different for two reasons. First, the way our core technology is built, it is broad spectrum with only one antigen – see diagram. Our unique antigen is the core of all gram-negative bacteria. This allows it to protect against numerous gram-negative bacterial diseases. Second, ENDO-VAC-Dairy is the only gram-negative vaccine not to have harmful active endotoxins. Endotoxins, also known as lipopolysaccharides, are not grown at all by our core antigen. This includes the toxin, Lipid A that plagues other gram-negative vaccines.
