

## PowerFloat Periotomes:

The rotating periotome has a rotating, beveled, cutting rod which is small enough to penetrate deep into a tooth's periodontal space as it cuts and destroys multiple, deeper attachment areas of periodontal tissue. This instrument has a collet which threads into the unguarded PowerFloat right angle attachment (chamfer burr attachment). The reciprocating periotome right angle attachment has a flexible cutting blade which is thin enough to penetrate deep into the periodontal space to destroy ligament attachment and assist in reforming the socket for extraction purposes. These advancements shorten the time required to extract equine cheek teeth.
