

1 Diagnostic Interpretation: Do your test results mean what you think they mean?

2 Drew R. Magstadt, DVM, MS

6

7 **Abstract**

8 In certain situations, diagnostic testing can play an integral role in beef and dairy operations
9 through accurate diagnosis of disease and reduction of disease transmission risk. The quality and
10 applicability of diagnostic results are dependent on the submission of proper samples and
11 appropriate interpretation of what test results mean, along with an understanding of what test
12 results do not mean, within the overall context of the situation. Clinical observations and gross
13 necropsy findings are critical to efficient and accurate diagnostic testing.

14

15

16 **The diagnostic process**

17 There is a wide range of reasons why a veterinarian/producer may be interested in
18 diagnostic testing including investigation of clinical disease, herd surveillance to reduce risk of
19 disease transmission, and satisfaction of export requirements. Whatever the reason for testing,
20 the entire diagnostic process starts with and depends on a well-defined diagnostic question: what
21 do you intend to learn? The diagnostic question drives everything else associated with the case.
22 Starting with a good diagnostic question allows us to choose the best test to answer that question,
23 select the best sample to collect for that test, and identify the most appropriate animals to sample.

24 How we preserve the sample also depends on which test is being run: does the sample need to be
25 fresh or formalin fixed, chilled or frozen, placed in another preservative (such as an EDTA tube
26 or a Trich pouch)? Collection of samples without your specific testing needs in mind can lead to
27 invalid results or reliance on test results that may not provide useful answers.

28

29 **Limitations of diagnostic tests and interpretation mistakes**

30 No single diagnostic test is perfect; all tests and testing methods have limitations that can
31 and should impact how we interpret results. Molecular testing is incredibly sensitive, yet this
32 presents potential issues when it comes to the detection of endemic/commensal pathogens or
33 recent modified live viral vaccination use. Bacterial culture requires live organism and can be
34 severely impacted by post mortem overgrowth or recent treatment; similar issues often arise with
35 isolation of commensal bacteria. Serologic evaluation of antibody is highly dependent on the
36 stage of disease and previous vaccination history. Toxicology/analytical chemistry testing can be
37 hard to interpret due to improper sample preservation or delays in collection/preservation; these
38 types of tests are often best performed using specific sample types that may be overlooked
39 during a routine necropsy (such as ocular fluid, bile, urine, or rumen content). Understanding the
40 limitations of diagnostic testing is an important part of result interpretation and can help establish
41 a proper degree of confidence.

42

43 **Gross necropsy interpretation**

44 In this author's opinion the single most important testing method available to practicing
45 veterinarians is their own powers of observation. Accurate observation, assessment, and
46 communication of clinical signs and gross necropsy findings is critical in disease investigations

47 to ensure the development of a case definition and creation of a legitimate list of differential
48 diagnoses. Classification of normal vs. abnormal findings through experience/repetition and the
49 thoroughness of clinical/necropsy examinations ensures that potentially important findings are
50 not overlooked or flat out missed. The term “pathognomonic” is probably overused but it can
51 absolutely apply to several common diseases/gross observations in cattle, as long as the finding
52 aligns with the context of the case. Issues arise when the term is applied to non-specific lesions
53 or diseases become mistakenly linked with findings that may or may not be abnormal at all. Your
54 gross necropsy findings should tell a coherent story of the disease process. And remember, “no
55 gross lesions observed” is a perfectly fine statement....as long as it is truly accurate.

57 **Laboratory resources**

58 Practicing veterinarians are encouraged to find and develop relationships with
59 knowledgeable diagnosticians, as well explore and fully utilize resources provided by their
60 diagnostic laboratory. Many labs publish sample collection guides, demonstration videos, and
61 examples of testing strategies on their website. Nearly all have extensive online testing
62 catalogues that include information such as the cost and testing schedule as well as preferred
63 sample types. User friendly web-based submissions have become widespread and should be
64 considered (especially for those that write in their own font); additional information such as
65 pictures or videos can be uploaded/included with the case, and several labs have shipping
66 programs that can reduce the cost of getting samples to the lab. All of these features are designed
67 to get accurate test results into the hands of practitioners in a timely manner, while reducing the
68 cost of inappropriate/unnecessary testing to the producer.
